ABSTRACT:

Method and apparatus for providing a timely, automated re-assignment of resources, such as peripheral devices, memory, and/or processing capacity, among a number of host data processing systems. In a preferred embodiment, the present invention allows peripheral devices, such as tape drives, to be configured as shareable units, and accessed by any participating host data processing system as the need arises. The invention preferably includes a central coordinating facility, which evaluates the device status information gathered, from each participating host data processing system. The device status information is used to determine which host data processing systems have free devices available for use. Within these constraints, the invention automatically orchestrates the re-assignment of selected peripheral devices from where they are not currently needed to where they are needed, with little or no operator interaction.

ABSTRACT:

A system for automatically responding to character-based messages is disclosed. A pattern database is defined with pattern definitions for matching input messages and response definitions for automatically responding to matching input messages. Patterns definitions include token definitions which define criteria for matching a portion of an input message. The pattern definitions further include pattern decisions that contain logical expressions which increases the flexibility in defining patterns to match messages. The response definitions include function definitions and optional function decisions. Functions to be performed in response to a matching message are specified in the function definitions, wherein performance of the specified functions is dependent upon evaluation of the function decisions.

ABSTRACT:

A system for automatically and variably responding to character-based messages is disclosed. With user specified input, a software tool creates a pattern database. The pattern database consists of pattern definitions for matching input messages and response definitions for automatically responding to matching input messages. Pattern definitions define criteria for matching an input message. The response definitions include function definitions and optional function decisions. Functions to be performed in response to a matching message are specified in the function definitions, wherein performance of the specified functions is dependent upon evaluation of the function decisions.

ABSTRACT:

A user specifies a hierarchical action tree via user input device and user interface element. The action tree is arranged in a tree of file directories, with each node of the tree corresponding to a file directory (or path). The user then specifies classes of patterns assigned to each node (directory) of the tree using data mining queries or pattern templates. Once the system is so initialized, the pattern templates and data mining queries are executed, retrieving the patterns specified by the user from a database. The retrieved patterns assigned to a node of

e b b cg b cc e

Record Display Form

the tree are then stored in a file in the corresponding file directory. The user may now act on the discovered patterns and use the organized file structure. A pattern discovery optimization element periodically checks if the database has changed substantially, and if it has re-executes the data mining queries and pattern templates which update the contents of the file structure accordingly.

ABSTRACT:

The present invention provides an improved boundary scan test system that can scan device scan paths in a parallel manner. In one embodiment, an improved method for processing a scan command from a pattern file is provided. The scan command is associated with (e.g., includes, points to) test device data that is to be scanned into physical system under test devices of a type specified by the command. Initially, a parallel device structure is acquired for the specified device type. The parallel device structure has one or more groups each identifying one or more parallel scan paths of devices within the physical system under test. A scan image is then prepared for each of the one or more groups whose one or more identified parallel scan paths include a device of the specified device type. For each group whose one or more scan paths has a device of the specified device type, a scan request, with the scan image prepared for the group, is then generated for that group. The scan request, when provided to a utility unit, causes the unit to scan in parallel the scan image into the one or more scan paths of the group in order to scan the test device data into the devices of the specified device type within the group.

ABSTRACT:

An automatic telephone, Internet or intranet community formation system that utilizes spoken words or matching search terms. The invention utilizes wireless and wired voice communications, database and list serve technology to archive and match users based upon their search terms entered into a telephone system or a search engine, Internet, intranet, extranet, local area network, wide area networked, wired, wireless or standalone computer. A community formation system refers to a means of inviting one or more persons to communicate via voice, email or other method and join in a discussion. Invitations to join would be sent via an email, SMS, instant messaging, phone, web browser, email or fax communication. The user would have control over whether s/he wanted to be invited into a community, the age of desired matches, the closeness or breadth of the matches, the duration of the community, and the type of community--voice or text. Also, users have the ability

ABSTRACT:

The invention is a software module configured for handling failure information from a large base of clients. The invention is configured for a four-stage network conversation between a client and a server. In the first stage, the module collects failure information and creates a string address. The string address is sent to the server, where the string address is compared to predefined string addresses. In the second stage, the client creates a record query with the failure information for the server. The record query is sent to the server and compared to predefined failure records. In the third stage, the client transfers additional failure information to the server, and the server acknowledges information transfer. In the fourth stage, the client sends a confirmation message to the server. When necessary, a predefined string address corresponding to the particular failure information is created on the server for subsequent reference by a stage one network conversation.

L2: Entry 12 of 29 File: USPT Dec 16, 2003

DOCUMENT-IDENTIFIER: US 6665824 B1
TITLE: System and method for handling a failure reporting conversation

CLAIMS:

2. The method of claim 1, further comprising the steps: in response to determining that the string address does not match a predefined string at the repository, creating a record query with failure information; accessing the repository to search a set of predefined failure records; and determining whether the record query matches a predefined failure record.

16. A method for handling a failure in an application program module, the method comprising the steps: collecting failure information from the application program module; creating a string address with the failure information; determining whether the string address matches a predefined string address at a repository; in response to determining that the string address matches a predefined string address at the repository, sending file content located at the matching string address from the repository to the application program module; in response to determining that the string address does not match a predefined string at the repository, creating a record query with failure information; accessing the repository to search a set of predefined failure records; determining whether the record query matches a predefined failure record; in response to determining that the record query does not match a predefined failure record, starting a preset counter for tracking needed additional failure information requests; creating a failure record with failure information corresponding to the record query; sending a request for additional failure information to the application program module; in response to determining that the record query matches a failure record, determining whether the preset counter is greater than zero; in response to determining that the preset counter is zero, sending a request for additional failure information to the application program module; sending additional failure information from the application program module to the repository; decrementing the preset counter; determining whether the preset counter is greater than zero; and in response to determining the preset counter is zero, creating a string address corresponding to the record query.

17. A computer-readable medium having computer-executable instructions for handling the reporting of a failure in a computer program, the computer-executable instructions performing the steps of: collecting failure information from the computer program: creating a string address with the failure information; determining whether the string address matches a predefined string address at a repository; in response to determining that the string address matches a predefined string address at the repository, sending file content located at the matching string address from the repository to the computer program; and in response to determining that the string address does not match a predefined string at the repository, creating a record query with failure information; accessing the repository to search a set of predefined failure records; and determining whether the record query matches a predefined failure record.

ABSTRACT:

An information retrieval system that represents the content of a language-based database being searched as well as the user's natural language query. In accordance with one aspect of the invention, the information retrieval system includes a non-real-time development system for automatically creating a database index having one or more content-based database keywords of the data base; and a real-time retrieval system that, in response to a user's natural language query, searches the keyword index for one or more content-based query keywords derived from the natural language query. The development system and the retrieval system morphologically, syntactically and linguistically analyze the data base and the natural language query, respectively, to generate the one or more database keywords and query keywords representing the content of the database and the natural language query, respectively. The development system includes a software development system for creating the database index utilizing a pattern dictionary that includes synonyms and skip words and a morphosyntactic dictionary that includes morphological and syntactic information for words in the natural language of the language-based database and the natural language query. In one embodiment, the retrieval system includes a natural language interface system for creating the one or more query keywords utilizing the pattern dictionary and the morphosyntactic dictionary. In one embodiment, the retrieval system also includes a query-index matcher for matching the one or more query keywords with the one or more database keywords.

ABSTRACT:

A terminal, such as character display unit or printer, has a character pattern memory region. A host system controls an operation of outputting a character to the terminal. In case of outputting a desired character to the terminal, firstly an examination is made at the side of the host system as to whether or not a character pattern corresponding to the desired character is stored in the character pattern memory region. When it is determined that the character pattern has not been stored in the character pattern memory region, the character pattern from the host system is loaded into the character pattern memory region.

L3: Entry 14 of 15 File: USPT Apr 21, 1998

DOCUMENT-IDENTIFIER: US 5742746 A
TITLE: Character output control method and apparatus for terminal

Detailed Description Text (9):
FIG. 3 is a block diagram corresponding to FIG. 1, and the flow of processing in the embodiment shown in FIG. 3 is similar to that of the flowchart of FIG. 2. As indicated within a functional block 10A in FIG. 3, this embodiment includes an interface 14 for designating the control method of the functional block 10A from the user or application program of the terminal 1. With an "initialize" request 40 and using system commands, the user of the terminal 1 sets the filename of the character-pattern database 30 and a size (the maximum number of the elements of a queue) and a management method (such as the LRU method or the FIFO method) for the character pattern cache emulation in the terminal control software and notifies the terminal control software of the use of the software ODL function. The notified terminal control software 10A prepares and initializes a memory for the character pattern cache emulation, and executes initialization for retrieving the character pattern database 30.

ABSTRACT:

A method for processing user-input that may include a command to abort a previously requested operation and typed-ahead data entered in anticipation of completion of the previously requested operation is disclosed. The user-input is represented by a value queued in a first queue by an operating system. According to the present invention, the value is removed from the first queue and examined to determine if it represents a command to abort the previously requested operation. If the value represents a command to abort the previously requested operation, the previously requested operation is aborted. If the value does not represent a command to abort the previously requested operation, the value is queued in a second queue, and, after completion of the previously requested operation, the value is removed from the second queue and associated with a display window to which user-input is focused at that time.

L3: Entry 12 of 15

DOCUMENT-IDENTIFIER: US 5900024 A
TITLE: Method for processing type-ahead input and operation-abort input

Detailed Description Text (57):
Consider now the message handler 600 and event loop 700 depicted in FIGS. 6 and 7, respectively, in the context of the FIG. 1 order entry screen 100. Assume that after entering the company name and pressing the key (or keys) which initiates the data retrieval operation, the order clerk types ahead the word "Pencils". Assume further that after the data retrieval operation is initiated at step 425 of message handler 600, no response from the database server is detected in step 430 for a number of iterations. In that case, steps 510, 515 and 610 of message handler 600 will be iteratively executed to remove messages indicating the typed-ahead characters (`P`, `e`, `n`, `c`, `i`, `l`, `s`) from the hardware event queue, confirm that none of the messages indicate a command to abort the data retrieval operation, and then queue the characters on the second queue. If, after the string "Pencils" has been queued on the second queue, data retrieval is completed, program execution proceeds from step 430 to step 435 where message handlers for the Company Name, ID#, Contact, Telephone and Address windows (110, 115,120,125 and 130) will be invoked to display the retrieved information designated for each window, and the keyboard focus will be shifted to the Item window 135. Thereafter, the message handler 600 will be exited and program execution will continue at step 710 of event loop 700.

Detailed Description Text (59):
Returning to the point in the example above where the order clerk typed ahead the string "Pencils", suppose further that the order clerk, realizing that the wrong company name had been entered, presses ctrl-break, ctrl-c or any other designated keys to abort the data retrieval operation (or, at least, to abort the routine awaiting a response from database server). Now, after repeated execution of steps 510, 515 and 610 to queue the string "Pencils" in the second queue, the message handler will remove the message indicating the abort command from the hardware event queue at step 510. Upon detecting the abort command at step 515, program execution will proceed to block 615 where the second queue is emptied. It will be appreciated that emptying the second queue after detecting an abort command may not be desirable in every application program and that step 615 therefore represents an optional operation. However, in the Order Entry Application of FIG. 1, aborting the data retrieval operation means leaving the keyboard focus in the Company Name window 110. Consequently, omitting to empty the second queue at step 615 would result in the characters "Pencils" being entered into the Company Name window 110 by event loop 700. By emptying the second queue in step 615 of message handler 600, this undesirable result is avoided.

ABSTRACT:

A method and apparatus are provided for processing reports. Upon system startup, a report server automatically starts one or more report processes. As client report commands are received from one or more client applications, the client report commands are assigned to one or more of the executing report processes. After a report is completed, the report process is automatically reinitialized and kept active to process another report. The report server automatically adjusts the number of active report processes based on the current report processing load requirements. According to another aspect of the present invention, a report queue is provided to store client report commands as they are received from the client applications. A report queue manager is also provided for externally managing the report queue.

TITLE: Method and apparatus for processing reports

Detailed Description Text (14):
Upon receiving the client report command 310(3) from the client application 302, the report server process 304 stores the client report command 310(3) in a report queue 312. The report server process 304 then determines whether the report process 306 is available for report processing. The report process 306 may not be available if a prior report is not yet completed. Once the report process 306 is available, the report server process 304 reads the report command 310(3) from the report queue 312 and then transmits a server report command 310(4) to the report process 306. After receiving the server report command 310(4), the report process 306 opens a report definitions file (RDF) 313 (FIG. 3A) which indicates what data is to be included in the report and how it is to be arranged. The report process 306 then issues DBMS commands 310(5) to the DBMS 308 to establish a session/connection to the DBMS 308 based on the database connection string contained in the server report command 310(4) and to retrieve data from the DB 309 (FIG. 3A). The DBMS 308 then transmits data 310(6) back to the report process 306. With this data, the report process 306 prepares a report and transmits it to its intended destination, such as a printer or file. However, according to other embodiments of the present invention, report processing may involve other tasks such as printing a previously prepared report or merging two or more previously prepared reports. As is typical of report processes, the report process 306 may write intermediate report files to a storage medium (not illustrated) as necessary to complete its report processing.

Detailed Description Text (18):
According to another embodiment of the present invention, upon startup, the report server process 304 automatically starts and initializes a minimum number of report processes 306 before client applications 302 begin issuing client report commands 310(3). If the number of unprocessed client report commands 310(3) in the report queue 312 greatly exceeds the processing capability of the currently executing report processes, then the report server process 304 dynamically allocates additional report processes 306 up to a maximum number of report processes 306. On the other hand, if because of reduced report demand, many of the report processes 306 are idle, the report server may terminate one or more idle report processes 306 to reduce processing overhead. Many report process allocation schemes may be used and the type and sophistication of the particular report process allocation scheme used depends upon the particular report system 300. When subsequent reports are processed by a particular report process 306, an (RDF) 313 only has to be opened if the report is a different report type than the last report processed. In addition, if based on the database connection string the same database 309 is to be used, then the existing DBMS 308 session/connection can be used, greatly reducing the startup time.
